### 1. Analysis of Multi-scale Optimization

By-example point pattern synthesis methods usually requires users to tune with the window size or kernel size parameters as shown previous state-of-the-art methods [\[MWT11\]](#page-1-0) [\[RÖM\\*15\]](#page-3-0) [\[TLH19\]](#page-3-1), to get satisfying synthesis results. Similarly, we use a multi-scale optimization strategy to preserve local and non-local structures for the synthesized patterns. Here we discuss the importance of multi-scale optimization and propose a way to tune with the two hyper-parameters which control the kernel size of our proposed Gabor features.

Single-scale vs. Multi-scale optimization. Fig. [1](#page-1-1) demonstrates that our multi-scale optimization is important for preserving both global and local structures. The value of  $\sigma$  is analogous to receptive field, higher  $\sigma$  value capture more global structure while low  $\sigma$  focuses more on local structures. As shown in the figure, optimizing with only  $\sigma_1$  results in a good global structure, but locally the points do not follow the regularity in the input. While optimizing only  $\sigma_2$ leads to the missing global structure. Therefore, multi-scale optimization firstly focuses on synthesizing pattern with good global structure and then refines the local structures during the decrease of σ value.

Tuning Hyper-parameters. As discussed, a pattern can express different level of structures and choosing an appropriate window or kernel size is a necessary step for high-quality synthesis. In some cases, choosing the parameters wrongly can lead to unpleasing synthesis results. Therefore, we propose a pragmatic way to tune the two hyper-parameters, namely  $c_1$  and  $c_2$ . As mentioned, most of the scenes use  $c_1$  in  $0.8 \pm 0.2$  and  $c_2$  are  $2.8 \pm 0.2$ . For a new test scene, as default, we start from  $c_1 = 0.6$ ,  $c_2 = 2.6$ . As shown in Fig. [2,](#page-2-0) when the number of points in the exemplar is small, the feature map of  $c_1$  may not show the overall structure of the point pattern and lead to over-blurring features. This can result in less visually pleasing results. When we start increasing  $c_1$  to be 0.6 and 0.8, the overall structure becomes more visible. Users can repeat this process until they are satisfied with the synthesized pattern. Fortunately, our method allows us to get satisfying synthesis results after few trials for most of the scenes. We summarize the parameters for all scenes in Table [1.](#page-0-0) As shown in the Table, the hyper-parameters are not so different across a large variety of scenes. This further demonstrates

<span id="page-0-0"></span>

that our method is robust to hyper-parameter setting and user can find a good solution without too much manual effort.

#### 2. Diverse Results

We show that our method inherently supports synthesizing diverse results given the same exemplar, using randomly initialized point patterns with different random seeds. Fig. [3](#page-2-1) shows three different outputs with different random initialization given the same input. Meanwhile, the overall structure looks similar to the exemplar. This also demonstrates that our method is robust to different initialization.

#### 3. Additional Results

## 3.1. Ablation Study

Number of channels. In the convolutional filtering step, we define the number of output channels *NC* to control the number of random

<span id="page-1-3"></span><span id="page-1-1"></span>*X. Huang, P. Memari, H.P. Seidel, G. Singh / Point-Pattern Synthesis using Gabor and Random Filters: Supplemental Material*

Figure 1: *Importance of multi-scale optimization. If only optimized with a single scale, the synthesized results (b), (c) will only capture either global or local structure.*

filters we use. Fig. [4](#page-3-2) shows how the number of output channels in the convolutional layer affects the final results. We observe less accurate synthesis results with less filters defined by number of output channels in the convolutional filters. Increasing the number of output channels increases the synthesis quality. We find that *NC* = 120 is a reasonable choice as increasing the number of channels beyond 120 brings marginal difference while being more computationally expensive.

Layer for Correlation loss computation. We also study the layer noted as *l* chosen for computing  $\mathcal{L}_{corr}$ . We use the 4*th* (*l* = 4) layer for computing L*corr*. Other options are to use output from layer  $l = 1, 2, 3$ . However,  $\mathcal{L}_{corr}$  becomes more computationally expensive with higher resolution feature maps. We observe out of memory issue while using the 1*st* or 2*nd* layer. Using the 3*rd* layer we get similar outputs as shown in Fig. [5,](#page-3-3) but the run-time is on average 6 times more than our choice.

#### 3.2. Qualitative Comparisons

Point patterns. We show more results in Fig. [8](#page-5-0) and Fig. [9](#page-6-0) for qualitative comparisons between ours methods and previous stateof-the-art methods. Note that these patterns are included in the user study. Among them, our method achieves highest user scores compared with previous state-of-the-art methods on most of the scenes.

Element patterns. For discrete element-based pattern expansion, we experiment with different variants of the input exemplars and the method of [\[RGF\\*20\]](#page-1-2). Fig. [6](#page-4-0) shows comparisons on 2-class patterns using our method, [\[RGF\\*20\]](#page-1-2) and [\[TLH19\]](#page-3-1). As DiffCompositing  $[RGF*20]$  use only the Gram loss  $\mathcal{L}_{gram}$  in their original paper, we test 2 more variants using their methods by including the Deep Correlation loss  $\mathcal{L}_{corr}$ . However, as shown in Fig. [7,](#page-4-1) we do not observe obvious improvement using their method, especially on the orange pattern with clear vertical structures in the middle column. On the other hand, our method performs better in terms of local and non-local structures. For patterns with more randomized structures, our method synthesizes patterns with less overlaps and closer to the exemplar's structure compared with [\[RGF\\*20\]](#page-1-2).

Further, we show in Fig. [11](#page-7-1) that our methods not only apply on discrete elements in 2*D*, but also elements with higher-dimensional

Table 2: *We perform user study and compute an average score across 28 users. We show the average score for each pattern where 1 is the worst and 5 is the best. Our method gets better score for all but one pattern. M, S, R refer to the figures in main paper, supplemental material and row number of the corresponding figure, respectively.*

features. As shown in Fig. [11,](#page-7-1) our method takes input point patterns with features including depth, scale and 3*D* orientation for synthesis. This allows us to use the synthesized patterns for object placement and pattern design not limited to 2*D* space.

## 3.3. User Study

Table [3](#page-3-4) shows the numbers of average scores from 28 participated users for the 14 point patterns used for our user study. Patterns we use are from Fig. 5 in the main paper, Fig. [8,](#page-5-0) Fig. [9](#page-6-0) and Fig. [10](#page-7-0) in the supplemental material.

Figure 6: *Discrete element-pattern expansion. We show 2-, 2 and 3-class examples from left to right and comparisons between [\[TLH19\]](#page-3-1)[\[RGF\\*20\]](#page-1-2) and our method from top to bottom.*

<span id="page-4-1"></span>

Figure 7: *Discrete element-pattern expansion with 4-class examples. We test two more variants of [\[RGF\\*20\]](#page-1-2) with only* L*corr and a weighted combination of* L*corr and* L*gram for fair comparisons with [\[TLH19\]](#page-3-1) and our method.*

<span id="page-5-1"></span><span id="page-5-0"></span>

## *X. Huang, P. Memari, H.P. Seidel, G. Singh / Point-Pattern Synthesis using Gabor and Random Filters: Supplemental Material*

Figure 8: *Additional comparisons between prior methods [\[MWT11\]](#page-1-0), [\[RÖM\\*15\]](#page-3-0), [\[TLH19\]](#page-3-1) and ours, respectively.*

<span id="page-6-0"></span>

*X. Huang, P. Memari, H.P. Seidel, G. Singh / Point-Pattern Synthesis using Gabor and Random Filters: Supplemental Material*

Figure 9: *Additional comparisons between prior methods [\[MWT11\]](#page-1-0), [\[RÖM\\*15\]](#page-3-0), [\[TLH19\]](#page-3-1) and ours, respectively.*

<span id="page-7-2"></span><span id="page-7-0"></span>

Figure 10: *Additional comparisons between prior methods [\[MWT11\]](#page-1-0), [\[RÖM\\*15\]](#page-3-0), [\[TLH19\]](#page-3-1) and ours, respectively.*

<span id="page-7-1"></span>

Figure 11: *Multi-attribute and multi-class point pattern synthesis results. We show* 2*-class examples from (a) to (c) and a* 6*-class example in (d). To visualize the patterns with multiple classes and attributes, we show* 2*D point patterns along with the rendering of* 5 *attributes including scale, depth and* 3*D orientation.*
